Introduction

Ask a home buyer to describe their dream house, and they probably won't begin with the height of the basement ceiling or the proximity to an east-west railroad. However, it is essential to review the data because it proves that there are many other influences in price negotiations than the number of bedrooms or a white-picket fence.

Data Synopsis

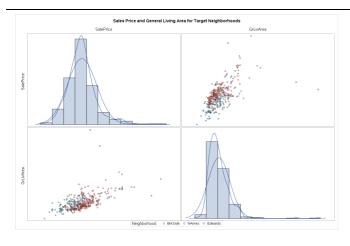

The Ames House dataset was compiled by Dean De Cock and contains 79 explanatory variables describing almost every aspect of residual home in Ames Iowa from 2006 to 2010. The data set contains 2930 observations involved in assessing home values.

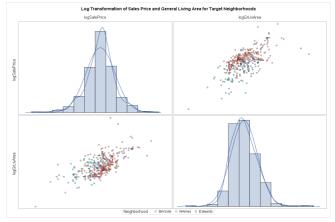

Data summary for North Ames, Edwards, and Brookside neighborhoods:

| Variable | N | N Miss | Minimum | Maximum | Mean | Median | Quartile Range |
|--------------|-----|--------|---------|---------|--------|--------|-----------------------|
| ld | 383 | 0 | 10 | 1460 | 744 | 729 | 744 |

Analysis Question 1

Restatement of Problem

Century 21 has commissioned Nixon, Friedrich, and Bourzikas to perform a study to derive insights regarding homes prices in Ames. Century focuses on three neighborhoods in Ames: "North Ames", "Edwards", and "Brookside". They would like to get an estimate of how the Sales Price of the house is related to the square footage of the living area of the house. Additionally, they would like to understand the relationship between sales price and the living area square footage, as well as investigating any relationship between sales price and that home's neighborhood.

Build and Fit the Model

In order to build and fit a model, an analysis must be performed to identify features of the dataset that are statistically significant in their relation to, and prediction of, the sales price.

When one of the predictor variables impacts how another predictor variable is related to the dependent variable. A multiple linear regression model in which the mean of the LogLivingArea depends linearly on the important of the

LogSalesPrice and all three Neighborhoods, allowing for different slopes and intercepts, is as follow:

In Assessing the Fit, the coefficient is interpreted by the following models utilizing the base formula: • Ames^SalesPrice = β 0 + β 1BrkSide + β 1Edwards + β 3:NAmes + β 4 (LogLivingAreaBrkSide) + β 5(LogLivingArea*Edwards) o β 0: The intercept in this model provides an estimate 8.49 of the logGrLivArwea (reference NAmes) with a logGrLivArwea of zero. Of course, this is extrapolation and does not have a clear, practical meaning. o β 1: This is the adjustment of the intercept for a Neighborhood BrkSide with respect to a NAmes Neighborhood. For a Living room of zero, the Neighborhood BrkSide has an estimated Sale Price Increases of -5. 16 (2^-2.58 back transformation) dollars per square foot less than the NAmes Livingroom. o β 1 This is the adjustment of the intercept for a Neighborhood Edwards with respect to a NAmes Neighborhood. For a Living room of zero, the Neighborhood Edwards has an estimated Sale Price Increases of -1.40 (2^-0.49 back transformation) dollars per square foot less than the NAmes Livingroom. o β 3: For each 1 unit increase in the Living Room of a NAmes, the estimated Sale Price increases 2^0.47 units o β 4: For each 1 unit increase in the Living Room Size of BrkSide, the estimated Sale Price increases 8.16 (2^0.35 Back transformed) dollars per square foot from the change with the NAmes. o β 5: For each 1 unit increase in the Living Room Size of Edwards, the estimated Sale Price increases 1.04 (2^0.05 Back transformed) dollars per square foot from the change with the NAmes.

Interrogate the Data

In reviewing the data, an analysis was performed using QQ Plots and Histograms, the linearity of the data is not in question due to the sample size, the data is right skewed and is not normally distributed as depicted, the data does not have equal standard deviations, and the data is independent of each other.

Because the assumptions in the data do not support evidence that will allow the study to continue due to data, transformation of the data was perfromed using the Log of the Sales Price and Log of the Grang Living Area. Upon this transforamtion, the linearity of the data is not in question, that is not strong evidence against normalizty of residuals looking at the histogram and QQ plot, the standard deviasion appear to be equel, and the data is indpependent. Additionally, there is a constant variance after the transformation occurred.

Additionaly, the it is assumped that the data is independent due to each house being unique to each neighnborhood.

After the transformation, the data was interrogated and a review of the studentized residuals and Cooks D was performed by running a fit diagnostic through our Proc Reg code. The review of Studentized residual identified one outliers that was related to a very large grand living room square footage and two outliers were related homes that have Sales price over 700,000 representing less than 0.13%. While these data points are low leverage with big residuals, Cooks D only show a mile problem. Due to the sample size, the Homes remained in the data set because these do not appear to affect the data.

Collinearity

Additionally, there is no collinearity in the data because Neighborhood and Grand Living are correlated with the Sales Price, if using differently each neighborhood variable as independent data. Since these variables are correlated with each other and the response variables, it is not difficult to parse out how each will impact the response variable independently.

R2

With only an R² .421 and an adjusted R² of .418, the fit of of the model of predicting sales price by Nieghborhood and Grand Living Room square foot, is not a good model. It is recommended that additional variables should be used to calculate a more accute Sales Price.

Outlier Analysis

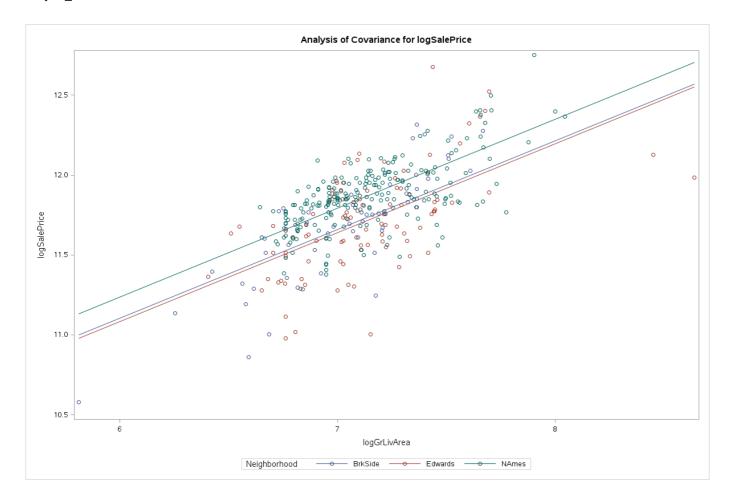

Model Comparison

After reviewing the models after and before the transformation, the R-Square is (0.51, 0.45, respectively) with a RMSE of (0.19, 28552.30, respectively) and a Coefficient Variance of (1.63, 20.68, respectively) ensuring the better fit is with the transformed data.

Adj R2

Parameters & Equations

- Estimates
- Interpretation
- Confidence Intervals

Variables: SalesPrice = SP LivingArea = LA

General Formula:

 $\hat{\mu}\{log(SP)\} = \beta_0 + \beta_1 Brookside + \beta_2 Edwards + \beta_3 Ames + \beta_4 (log(LA) Brookside) + \beta_5 (log(LA) Edwards)$

Ames (North):

$$\hat{\mu}\{log(SP_{Ames})\}\ = \beta_0 + \beta_1 Brookside + \beta_2 Edwards + \beta_3 Ames + \beta_4 (log(LA) Brookside) + \beta_5 (log(LA) Edwards)$$

Brookside:

$$\hat{\mu}\{log(SP_{Brookside})\} = \beta_0 + \beta_1 Brookside + \beta_2 Edwards + \beta_3 Ames + \beta_4 (log(LA) Brookside) + \beta_5 (log(LA) Edwards)$$

Edwards:

$$\hat{\mu}\{log(SP_{Edwards})\} = \beta_0 + \beta_1 Brookside + \beta_2 Edwards + \beta_3 Ames + \beta_4 (log(LA) Brookside) + \beta_5 (log(LA) Edwards)$$

Conclusion

To interpret the model, a change in Living Room Square Feet is a doubled increase. For the neighborhood with approximately the same mass, it is estimate that a 10-fold increase in the Living Area Square feet is associated with a XX which is a 83.2% increase in the median Sales Price of the neighborhood. (P value < 0.001). At a 95% confidence intervals for the increase in sales price of XX = CI which equates to an estimated increase between X% and X%.

Analysis Question 2

Restate Problem

Our objective is to build the most predictive model for sale prices of homes in Ames, lowa using only the tools learned through week 14 of MSDS 6371. We are to produce and compare four models: forward selection, backward elimination, stepwise selection, and a custom model. Models are to be evaluated on adjusted R^2, CV PRESS, and Kaggle score. We want the model that does the best job predicting future prices (that is, best Kaggle score wins).

Model Selection

Backward elimination, forward selection, stepwise selection, and custom models were built for this question. All models were built using log-log transformed data (log of SalePrice and log of GrLivArea). Forward selection and stepwise selection had comparable Kaggle scores. Based on interpretability, the Forward Selection Model was chosen.

Check Assumptions

Based on the lack of overwhelming evidence to support the assumptions, a number of transformations were considered and a decision was made to use a log-log transformation as the basis of the most predictive model.

Linearity

We know from the previous question that SalePrice is linearly correlated with some of the explanatory variables (size, for example), but it is unlikely to be correlated with all of them.

Heteroscedacity

There is some visual evidence against constant variance. With the large number of observations, visual inspection becomes more challenging.

Check Normality

A histogram of saleprice across all neighborhoods shows evidence of right skewness.

Independence

Although, homeowners are free to price their homes as they wish and buyers can make whatever offer they choose, there is no way to say with much certainty that home prices are truly independent.

Residual Diagnostics

Outlier Analysis

Two observations had CooksD values significantly higher than other observations.

And no observations appeared to be particularly high leverage so we can proceed without the need to removing any observations prior to modelling.

Comparing Competing Models

| Predictive Models | Adjusted R2 | CV PRESS | Kaggle Score |
|--------------------------|-------------|----------|--------------|
| Forward | .8501 | 31.18449 | .14880 |
| Backward | .9350 | 31.67571 | .21225 |
| Stepwise | .9206 | 19.14915 | .14880 |

CUSTOM

Best model: Forward selection

The "best" model in this situation is one that has a high degree of predictable power and is easy to interpret. That model is the forward selection model.

At five explanatory variables, the forward selection model is relatively small. It includes coefficients for OverallCond, OverallQual, BsmtFinSF1, Neighborhood and logliv. In other words, it predicts that the price of a home is a function of its location, size, and overall condition.

Each neighborhood has a coefficient that acts as a multiplier for a % increase or decrease in the mean SalePrice relative to the Veenker Neighborhood (reference level selected by SAS).

The equation for this model is the following:

$$\hat{\mu}\{log(SalePrice)\} = \beta_0 + \beta_1 OverallQual + \beta_2 OverallCond + \beta_3 BsmtFinSF1 + \beta_4 log(GrLivArea) + \beta_5 Neighborhood$$

What this means in real world terms is that a 10% increase in the above ground living area should result in an ~4.4% increase in price ($1.1^{\beta_4}=1.1^{0.455}=1.044$) due to log transforming the SalePrice and the GrLivArea variable.

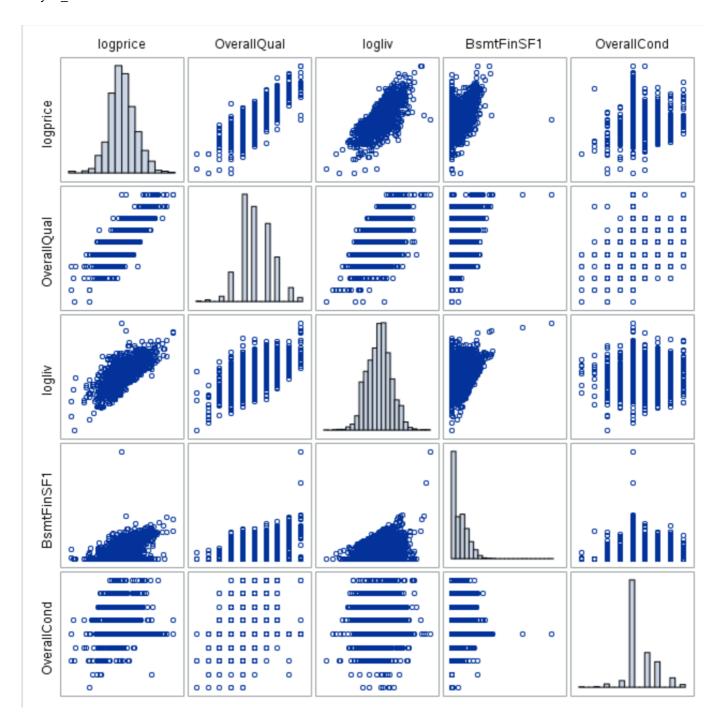

The selection of Neighborhood impacts the mean selling price by the relative percentage of e^{β_5} . The mean price for Neighborhoods with negative coefficients goes down relative to the Veenker reference neighborhood.

For each unit increase in the OverallQual score, the mean selling price will increase by approx. 10% ($e^{\beta_1}=e^{0.0956}=1.10$).

For each unit increase in OverallCond score, the mean selling price will increase by approx. 4.9% ($e^{\beta_2}=e^{0.0477}=1.0488$)

For each unit increase in BsmtFinSF1, the mean selling price will increase by approx. 0.0012% ($e^{\beta_3}=e^{0.000118}=1.000118007$).

Visually we can see that $\log(GrLivArea)$ is the strongest predictor of price followed by OverallQual. This makes sense conceptually. It's reasonable to assume people will pay more for a big, nice home.

The GLMSELECT Procedure

| | Forward Selection Summary | | | | | | | | | | | |
